Now that we have established a condition for which g(x) has a unique fixed point in I, there remains the problem of how to find it. The technique employed is known as fixed-point iteration.

Basic Approach

• To approximate the fixed point of a function g, we choose an initial approximation p_0 and generate the sequence $\{p_n\}_{n=0}^{\infty}$ by letting $p_n = g(p_{n-1})$, for each $n \ge 1$.

Basic Approach

- To approximate the fixed point of a function g, we choose an initial approximation p_0 and generate the sequence $\{p_n\}_{n=0}^{\infty}$ by letting $p_n = g(p_{n-1})$, for each $n \ge 1$.
- If the sequence converges to *p* and *g* is continuous, then

$$p=\lim_{n o\infty}p_n=\lim_{n o\infty}g(p_{n-1})=g\left(\lim_{n o\infty}p_{n-1}
ight)=g(p),$$

and a solution to x = g(x) is obtained.

A Single Nonlinear Equation

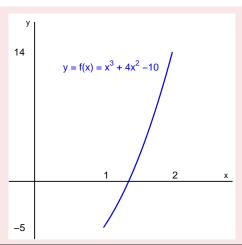

Example 1

The equation

$$x^3 + 4x^2 - 10 = 0$$

has a unique root in [1,2]. Its value is approximately 1.365230013.

- For example, to obtain the function g described in part (c), we can manipulate the equation $x^3 + 4x^2 10 = 0$ as follows:

$$4x^2 = 10 - x^3$$
, so $x^2 = \frac{1}{4}(10 - x^3)$, and $x = \pm \frac{1}{2}(10 - x^3)^{1/2}$.

Functional (Fixed-Point) Iteration

A Crucial Question

 How can we find a fixed-point problem that produces a sequence that reliably and rapidly converges to a solution to a given root-finding problem?

A Crucial Question

- How can we find a fixed-point problem that produces a sequence that reliably and rapidly converges to a solution to a given root-finding problem?
- The following theorem and its corollary give us some clues concerning the paths we should pursue and, perhaps more importantly, some we should reject.

Convergence Result

Let $g \in C[a,b]$ with $g(x) \in [a,b]$ for all $x \in [a,b]$. Let g'(x) exist on (a,b) with

$$|g'(x)| \le k < 1, \quad \forall x \in [a, b].$$

Functional (Fixed-Point) Iteration

Convergence Result

Let $g \in C[a, b]$ with $g(x) \in [a, b]$ for all $x \in [a, b]$. Let g'(x) exist on (a, b) with

$$|g'(x)| \le k < 1, \quad \forall x \in [a, b].$$

If p_0 is any point in [a, b] then the sequence defined by

$$p_n = g(p_{n-1}), \qquad n \geq 1,$$

will converge to the unique fixed point p in [a, b].

Proof of the Convergence Result

• By the Uniquenes Theorem, a unique fixed point exists in [a, b].

- By the Uniquenes Theorem, a unique fixed point exists in [a, b].
- Since g maps [a, b] into itself, the sequence $\{p_n\}_{n=0}^{\infty}$ is defined for all $n \ge 0$ and $p_n \in [a, b]$ for all n.

- By the Uniquenes Theorem, a unique fixed point exists in [a, b].
- Since g maps [a, b] into itself, the sequence $\{p_n\}_{n=0}^{\infty}$ is defined for all $n \ge 0$ and $p_n \in [a, b]$ for all n.
- Using the Mean Value Theorem $\underbrace{\quad\quad}$ and the assumption that $|g'(x)| \le k < 1, \forall x \in [a, b]$, we write

$$|p_n - p| = |g(p_{n-1}) - g(p)|$$

- By the Uniquenes Theorem, a unique fixed point exists in [a, b].
- Since g maps [a, b] into itself, the sequence $\{p_n\}_{n=0}^{\infty}$ is defined for all $n \ge 0$ and $p_n \in [a, b]$ for all n.
- Using the Mean Value Theorem $\underbrace{\text{MVI}}$ and the assumption that $|g'(x)| \le k < 1$, $\forall x \in [a, b]$, we write

$$|p_n - p| = |g(p_{n-1}) - g(p)|$$

 $\leq |g'(\xi)| |p_{n-1} - p|$

Proof of the Convergence Result

$$\leq k^2 |p_{n-2} - p|$$

$$\leq k^n |p_0 - p|$$

Proof of the Convergence Result (Cont'd)

Applying the inequality of the hypothesis inductively gives

$$|p_n - p| \leq k |p_{n-1} - p|$$

$$\leq k^2 |p_{n-2} - p|$$

$$\leq k^n |p_0 - p|$$

Since k < 1,

$$\lim_{n\to\infty}|p_n-p|\leq\lim_{n\to\infty}k^n\,|p_0-p|=0,$$

and $\{p_n\}_{n=0}^{\infty}$ converges to p.

Determine the Parameters of the Problem

Example: $g(x) = g(x) = 3^{-x}$

Consider the iteration function $g(x) = 3^{-x}$ over the interval $[\frac{1}{3}, 1]$ starting with $p_0 = \frac{1}{3}$. Determine a lower bound for the number of iterations n required so that $|p_n - p| < 10^{-5}$?

Determine the Parameters of the Problem

Note that $p_1 = g(p_0) = 3^{-\frac{1}{3}} = 0.6933612$ and, since $g'(x) = -3^{-x} \ln 3$, we obtain the bound

$$|g'(x)| \le 3^{-\frac{1}{3}} \ln 3 \le .7617362 \approx .762 = k.$$

Use the Corollary

Use the Corollary

Therefore, we have

$$|p_n - p| \le \frac{k^n}{1 - k} |p_0 - p_1|$$

Use the Corollary

Therefore, we have

$$|p_n - p| \le \frac{k^n}{1 - k} |p_0 - p_1|$$
 $\le \frac{.762^n}{1 - .762} \left| \frac{1}{3} - .6933612 \right|$

Use the Corollary

Therefore, we have

$$|p_n - p| \leq \frac{k^n}{1 - k} |p_0 - p_1|$$

$$\leq \frac{.762^n}{1 - .762} \left| \frac{1}{3} - .6933612 \right|$$

$$\leq 1.513 \times 0.762^n$$

Use the Corollary

Therefore, we have

$$|p_n - p| \leq \frac{k^n}{1 - k} |p_0 - p_1|$$

$$\leq \frac{.762^n}{1 - .762} \left| \frac{1}{3} - .6933612 \right|$$

$$\leq 1.513 \times 0.762^n$$

We require that

$$1.513 \times 0.762^n < 10^{-5}$$
 or

$$x=g_2(x)=\sqrt{\frac{10}{x}-4x}$$

Iteration for $x = g_2(x)$ is Not Defined

It is clear that $g_2(x)$ does not map [1,2] onto [1,2] and the sequence $\{p_n\}_{n=0}^{\infty}$ is not defined for $p_0=1.5$. Also, there is no interval containing p such that

$$\left|g_2'(x)\right|<1$$

since

$$q'(1) \approx -2.86$$

$$g'(p) \approx -3.43$$

and g'(x) is not defined for x > 1.58.

Solving
$$f(x) = x^3 + 4x^2 - 10 = 0$$

$$x = g_3(x) = \frac{1}{2} \sqrt{10 - x^3}$$

By differentiation,

$$g_3'(x) = -\frac{3x^2}{4\sqrt{10-x^3}} < 0$$

for $x \in [1, 2]$

and so $g=g_3$ is strictly decreasing on [1,2].

Solving

$$x = g_3(x) = \frac{1}{2} \sqrt{10 - x^3}$$

By differentiation,

$$g_3'(x) = -\frac{3x^2}{4\sqrt{10-x^3}} < 0$$
 for $x \in [1,2]$

and so $g=g_3$ is strictly decreasing on [1,2]. However, $|g_3'(x)|>1$ for x>1.71 and $|g_3'(2)|\approx -2.12$.

Solving

and so $g=g_3$ is strictly decreasing on [1,2]. However, $|g_3'(x)| > 1$ for x > 1.71 and $|g_3'(2)| \approx -2.12$. A closer examination of $\{p_n\}_{n=0}^{\infty}$ will show that it suffices to consider the interval [1,1.7] where $|g_3'(x)| < 1$ and $g(x) \in [1,1.7]$ for $x \in [1,1.7]$.

Iteration for $x = g_4(x)$ Converges (Moderately)

By differentiation,

$$g_4'(x) = -\sqrt{\frac{10}{4(4+x)^3}} < 0$$

and it is easy to show that

$$0.10 < |g_4'(x)| < 0.15$$

$$\forall x \in [1,2]$$

$$x=g_4(x)=\sqrt{\frac{10}{4+x}}$$

Iteration for $x = g_4(x)$ Converges (Moderately)

By differentiation,

$$g_4'(x) = -\sqrt{\frac{10}{4(4+x)^3}} < 0$$

and it is easy to show that

$$0.10 < |g_4'(x)| < 0.15$$
 $\forall x \in [1, 2]$

The bound on the magnitude of $|g'_4(x)|$ is much smaller than that for $|g'_3(x)|$ and this explains the reason for the much faster convergence.

Iteration for $x = g_5(x)$ Converges (Rapidly)

For the iteration function $g_5(x)$, we obtain:

$$g_5(x) = x - \frac{f(x)}{f'(x)} \Rightarrow g'_5(x) = \frac{f(x)f''(x)}{[f'(x)]^2} \Rightarrow g'_5(p) = 0$$
